September 2013

1 BACKGROUND

Air pollutant emission factors from conventional gasoline and diesel vehicles are needed to construct baseline emission scenarios for well-to-wheels (WTW) analysis of the air pollutant emissions of both conventional and advanced vehicle technologies. Air pollutant emission factors vary over time with advances in engine technologies, changes in fuel specification regulations, deterioration due to vehicle mileage accumulation, implementation of tighter on-road emission controls such as inspection and maintenance (I/M) programs, and adoption of advanced emission control technologies, such as second-generation onboard diagnostics (OBD II), selective catalytic reduction, diesel particulate filters, and diesel oxidation catalysts. Therefore, up-to-date air pollutant emission factors from vehicle operations that reflect the impacts of recent advances in vehicle technologies and emission control regulations are needed for an improved understanding of pump-to-wheels emissions and for the evaluation of the air pollutant emission reduction potentials of alternative vehicle technologies.

Efforts were made to estimate the vehicle criteria air pollutant emission factors using EPA's MOBILE6.2 and California Air Resource Board's EMFAC models in a previous Argonne National Laboratory study (Brinkman et al., 2005). The present document aims to update the vehicle model year (MY)-based emission factors of various air pollutants from vehicle operation activities involving various vehicle technologies, using the EPA's latest mobile-source emission factor model, the Motor Vehicle Emission Simulator (MOVES) (EPA, 2013a). The lifetime mileage-weighted average emission factors for vehicles of each MY between 1990 and 2020, over their lifetime of over 30 years, are to be estimated. The probability distribution functions (PDFs) of the emission factors will also be updated for uncertainty analysis purposes. The updated emission factors and their PDFs are to be used by the GREETTM (Greenhouse gases, Regulated Emissions, and Energy use in Transportation) model, which was originally developed to evaluate the fuel-cycle (or WTW) energy use and emissions of various transportation technologies (Wang, 1999).

2 METHODOLOGY AND DATA

2.1 The MOVES Model

We used MOVES2010b, the latest version of the EPA's modeling tool for estimating emissions from highway vehicles. Specifically, emission factors from gasoline and diesel passenger cars, light-duty and heavy-duty trucks, and motorcycles were estimated for six criteria air pollutants, carbon monoxide (CO), nitrogen oxides (NO_x), sulfur oxides (SO_x), volatile organic compounds (VOCs), particulate matter with diameters of 10 micrometers or less (PM_{10}), and particulate matter with diameters of 2.5 micrometers or less ($\text{PM}_{2.5}$), as well as the major components of particulate matter, i.e., black carbon (BC), organic carbon (OC), and sulfate. In addition, emission factors for two non-carbon dioxide (CO_2) greenhouse gases, methane (CH_4) and nitrous oxide (N_2O), were estimated. The development of MOVES has been based on the analysis of millions of emission test results and considerable advances in the EPA's understanding of vehicle emissions (EPA, 2013b).

Over the last ten years, EPA's in-use emission data, reflecting standards and technologies such as Tier 2, OBD II, and enhanced evaporative emission control systems, have dramatically improved. For MOVES2010b, EPA has been able to carefully study these newer technologies, examining millions of results for light-duty vehicles. Also in support of MOVES2010b development, the EPA conducted a landmark study of PM emissions, testing nearly 500 gasoline-fueled light-duty cars and trucks in Kansas City, Missouri, in what is currently the largest such study ever conducted. With the testing of more than 400 in-use trucks and the incorporation of additional emission measurement data from heavy-duty diesel crankcase ventilation and from extended idling—two emission processes that were relatively unstudied at the time MOBILE6.2 was developed—EPA's understanding of emissions from heavy-duty vehicles has continued to improve since MOBILE6.2 was issued. Therefore, MOVES2010b replaces MOBILE6.2, the previous model for estimating on-road mobile-source emissions, as EPA's best available tool for quantifying criteria pollutant and precursor emissions from light- and heavy-duty vehicles (EPA, 2013b).

In the development of MOVES, EPA has transitioned away from the standard MOBILE6 vehicle classes (based on gross vehicle weight rating, or GVWR) and instead characterizes vehicles by source type, based on their expected mode of operation. However, the emission factors contained within the model are still primarily aggregated on a vehicle class/weight basis (ERG, 2011). An internal module of MOVES called Source Bin Generator maps the source types in MOVES to GVWR-based vehicle classes. Table A1 in the Appendix summarizes the vehicle type mapping in MOVES. MOVES is also capable of generating emission factors by source classification code, which corresponds to GVWR-based vehicle classes.

2.2 MOVES Inputs

Vehicle engine technologies, driving cycles on various road types, fuel specifications and quality, I/M programs, emission control technologies, ambient meteorological conditions, and

deterioration effects due to accumulated mileage are among the many factors that affect air pollutant emissions from vehicle operations. Therefore, the input parameters required by MOVES include population and vehicle miles traveled (VMT) by vehicle type; temporal and spatial distributions of VMT by vehicle type; age distribution and average speed distribution by vehicle type; road type distribution; ramp fractions and types; formulations and market shares of fuels; I/M programs by vehicle type by MY; and ambient meteorological conditions. To this end, we used the “default” input database in MOVES2010b that summarizes all required emission-relevant information for the entire U.S. to estimate the U.S. average emission factors of a specific MY vehicle over the calendar years (CYs) of the vehicle’s lifetime, except for information on evaporative VOC emissions, which requires hourly temperature and relative-humidity profiles and fuel specifications for hourly-based simulation. The data for the default database come from many sources, including EPA studies, Census Bureau vehicle surveys, Federal Highway Administration travel data, and other federal, state, local, industry and academic sources (EPA, 2012). The national-level MOVES2010b runs were performed for each CY from 1990 to 2050, to provide emissions and VMT results for each CY of each MY vehicle’s lifetime from 1990 to 2020. For evaporative VOC emissions, which are produced through fuel vapor venting, permeation, and leak processes, we performed the state-level MOVES2010b simulations in Illinois and Texas with state-specific hourly meteorological data and fuel types and fuel specifications, which are available in the default database in MOVES2010b. Such state-level simulations were performed for January and July representing winter and summer, respectively, to evaluate the seasonal and fuel impacts on evaporative VOC emissions, because both meteorological conditions and fuel specifications significantly differ between summer and winter. These state-level MOVES2010b simulations were performed for each CY from 1990 to 2050 to generate evaporative VOC emissions and the corresponding VMT for each CY of each MY vehicle’s lifetime from 1990 to 2020. Finally, the evaporative VOC emission factors in both states in both months were averaged to represent the U.S. national average evaporative VOC emission factors.

2.3 Development of Probability Distribution Functions of Vehicle Emission Factors

Vehicle emission factors vary with location and time, because of spatial variation in vehicle driving cycles, road distributions, fuel specifications, and ambient temperature and humidity, as well as deterioration of engine operations over time. We conducted state-level simulations with MOVES2010b for MY 2010 vehicles to understand the spatial variation in emission factors due to state-specific driving cycles, road type distribution, ramp fractions, formulations and market shares of fuels, I/M programs, and ambient meteorological conditions. Noticeable variation in emission factors of tailpipe pollutants among states is revealed by the state-specific modeling results obtained with MOVES2010b. This agrees with our expectation of the impacts of the various location-specific influencing factors on emission factors. Meanwhile, deterioration due to engine aging with mileage accumulated over time contributes to temporal variation in emission factors. Taking CO emission factors as an example, Figure 1 shows the spatial and temporal variation in CO emission factors of MY 2010 passenger cars. To incorporate these spatial and temporal variations in emission factors into the lifetime weighted average emission factors for each MY vehicle, which are necessary for stochastic simulations for uncertainty diagnosis, we developed the VMT-weighted average PDFs of emission factors for

each MY vehicle on the basis of the state-specific emission factors and annual VMT in each CY over the lifetime of a particular MY vehicle. These PDFs capture the effects of changes in vehicle driving cycles, road distributions, fuel specifications, and ambient temperature and humidity, and the effects of deterioration of engine operations, on the pollutant emission factors nationwide over the lifetime of a particular MY vehicle. It is noted that we scaled the state-specific emission factors in CYs beyond 2010 on the basis of (a) the 2010 emission factors and (b) the ratios of the national average emission factors beyond 2010 to those in 2010. The state-specific VMTs of the vehicles in CYs beyond 2010 are scaled by assuming that the share of each state's VMT relative to the national total VMT would remain the same as in 2010. Using this approach, the simulated national average emission factors in each CY over the lifetime of each MY vehicle are further allocated to the state level, and the potential distribution type of all the state-specific emission-factor data points in each CY over the lifetime of each MY vehicle is tested, with the state-specific VMT in the corresponding CY as the weighting factor, against 55 possible distribution types ranked by their Kolmogorov-Smirnov, Anderson-Darling and Chi-Squared test statistics as obtained with the Easyfit toolbox (Mathwave, 2013). The statistically best PDF is determined on the basis of the goodness-of-fit rank of all the possible distribution types.

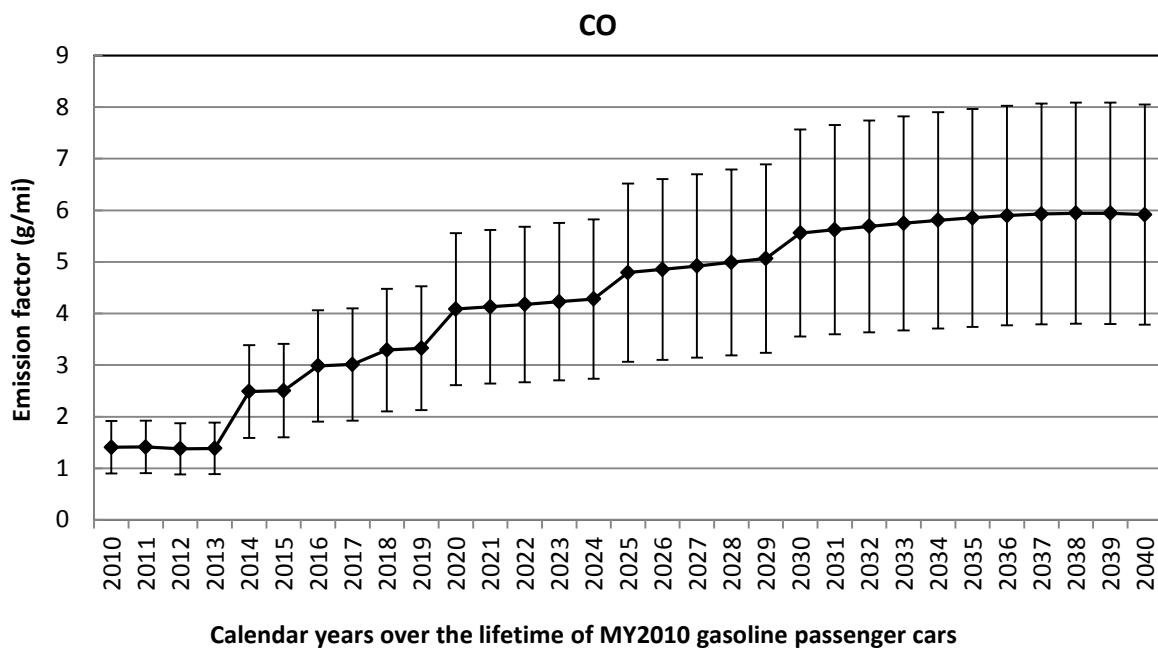

Figure 1 Spatial and temporal variation in CO emission factors of MY 2010 gasoline passenger cars over their lifetime CYs. Error bars depict the spatial variation among states.

3 RESULTS

3.1 Lifetime Mileage-weighted Average Emission Factors by Model Year

Using the emission factors in each CY during the lifetime of every MY vehicle from 1990 to 2020 generated by MOVES2010b for U.S. average conditions, we calculated the annual VMT weighted average emission factors by MY for gasoline and diesel passenger cars, light-duty and heavy-duty trucks, and motorcycles, as shown in Tables A2 to A23, using Equation (1):

$$EF_{i,j,MY} = \frac{\sum_{CY}^{CY+30} (VMT_{i,CY} \times EF_{i,j,CY})}{\sum_{CY}^{CY+30} VMT_{i,CY}},$$

where $EF_{i,j,MY}$ is the VMT-weighted lifetime emission factor of pollutant j from vehicle type i for MY; $VMT_{i,CY}$ is the VMT of vehicle type i for each CY during the lifetime of the MY vehicle; and $EF_{i,j,CY}$ is the emission factor of pollutant j from vehicle type i for each CY during the lifetime of the MY vehicle.

VMT shares and emission shares by vehicle type are important for understanding the contributions of various types of vehicles to emissions of each specific pollutant that is of concern for air quality and human health, and are critical evidence to support policy-making for emission control. Therefore, we analyzed the lifetime VMT and pollutant emission shares of various vehicle types by MY, as shown in Tables A24 and A25, respectively.

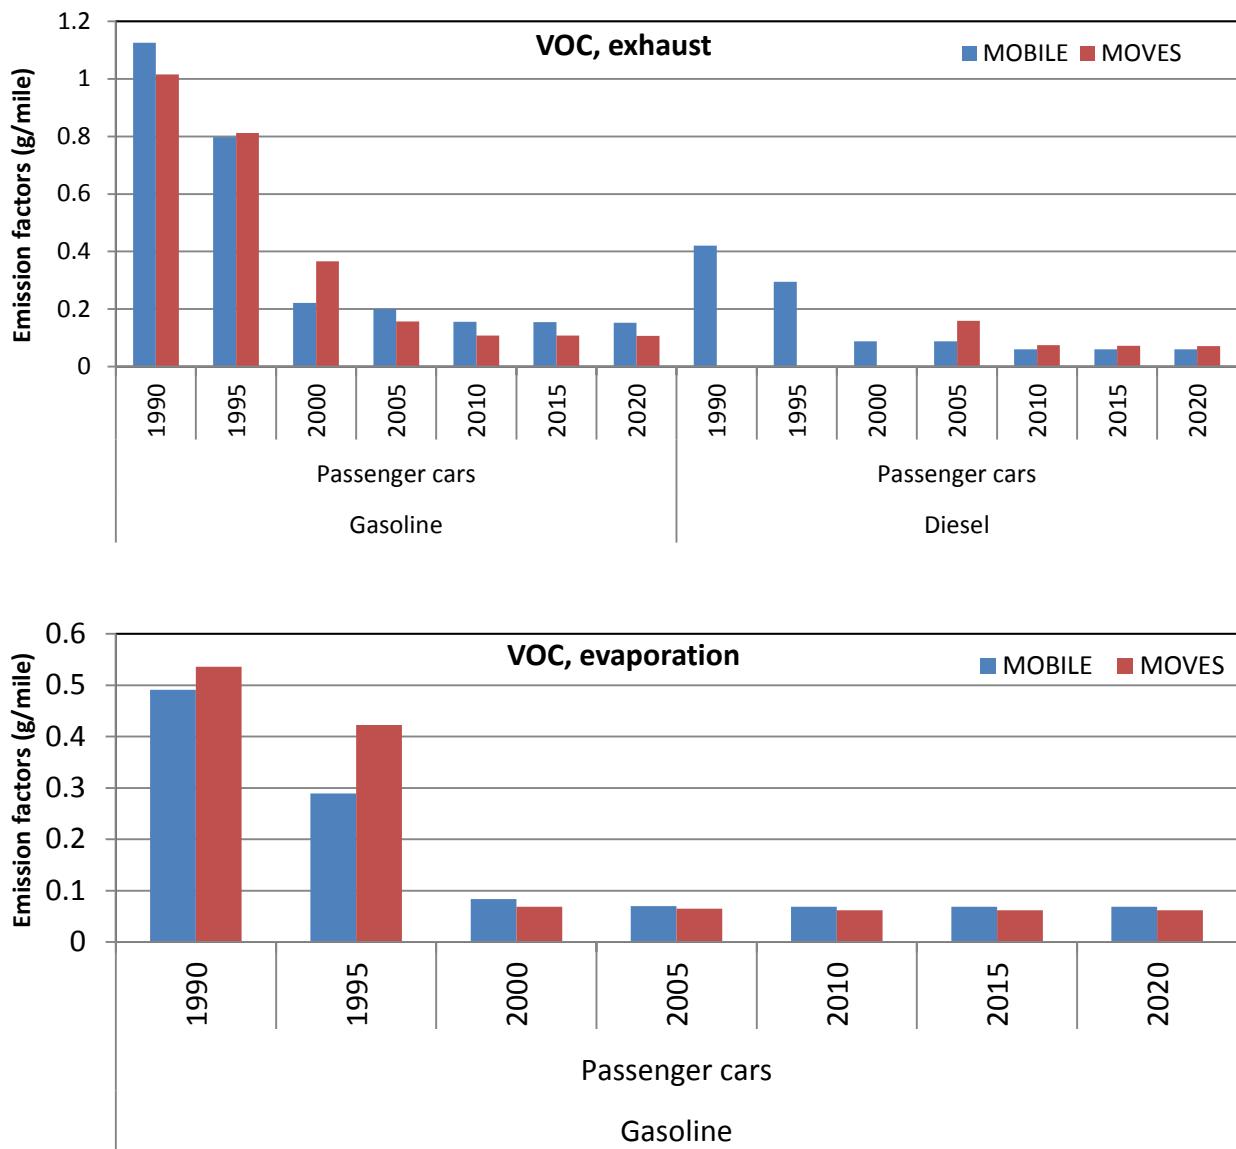

3.2 Probability Distribution Functions of Vehicle Air Pollutant Emission Factors

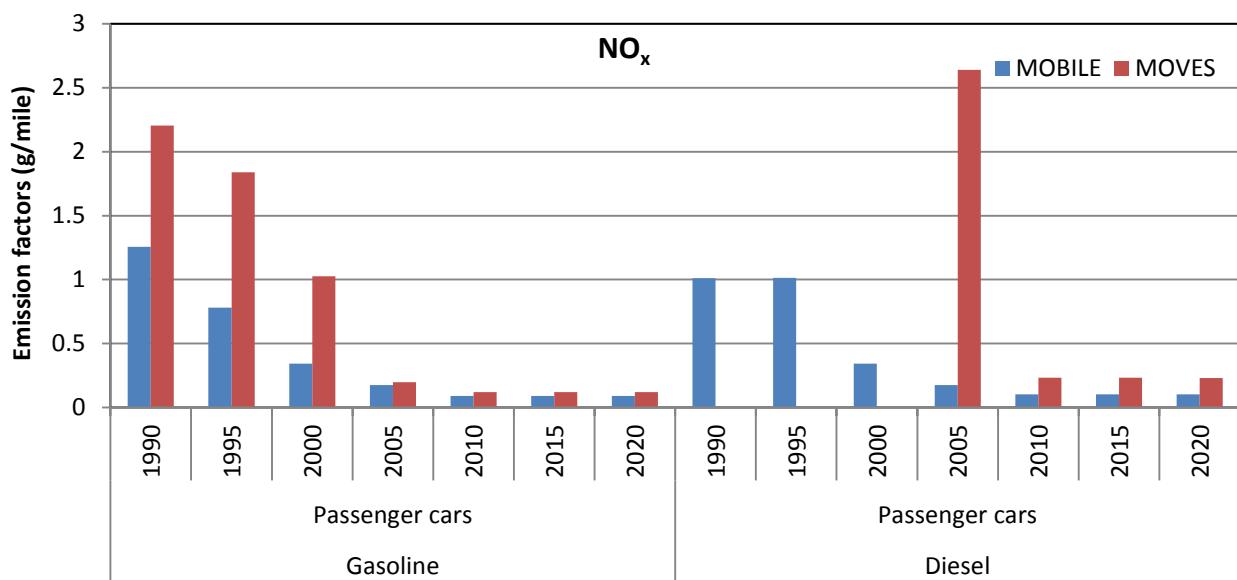

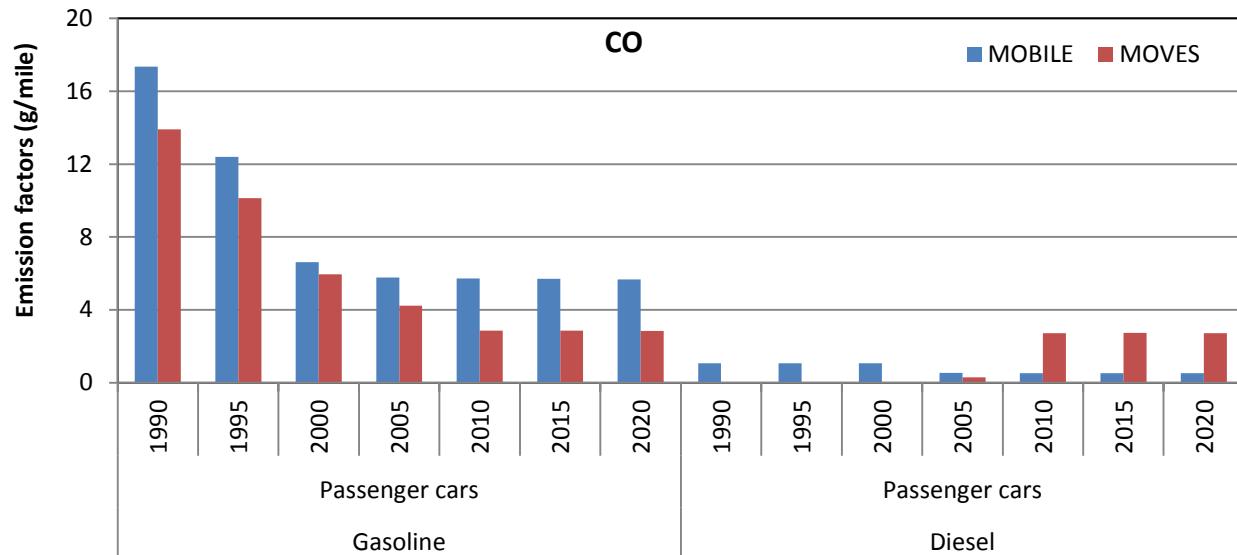

The PDFs of lifetime VMT-weighted average emission factors for each MY gasoline passenger cars are summarized in Table A26.

3.3 Comparison with Previous Emission Factors in GREET

The previous vehicle air pollutant emission factors in GREET were determined by the average of simulations from both the MOBILE6.2 and EMFAC2002 models (Brinkman et al., 2005). Owing to significant differences between the two models' simulations, the average emission factors in GREET are not representative of the MOBILE6.2 simulations and therefore are not directly comparable to the MOVES2010b results in this work. Instead, we compared the MOVES2010b-based emission factors to the previous simulations from MOBILE6.2. The MOVES2010b simulations generally produce lower CO and VOC emission factors and higher

NO_x emission factors for gasoline passenger cars than the MOBILE6.2 simulations, as shown in Figure 2; this result is consistent with EPA's findings (EPA, 2013b). On the other hand, the CO and VOC emission factors for gasoline light-duty vehicles, diesel passenger cars, and diesel light-duty vehicles are higher for MOVES2010b than for MOBILE6.2. Evaporative VOC emission factors simulated by MOVES2010b are higher than previous estimations by MOBILE6.2 for MY 1995 and earlier passenger cars, and are slightly lower than those for MY 2000 and newer passenger cars. The PM_{10} , $\text{PM}_{2.5}$ and NO_x emission factors simulated by MOVES2010b are significantly higher compared to MOBILE6.2 for both passenger cars and light-duty vehicles. These differences agree with EPA's findings as well. On the basis of newly available measurement data, the new results generated by MOVES2010b, which models the impacts of low ambient temperatures, vehicle speed, vehicle load, deterioration effects, and extended idle activity as a fraction of total activity on in-use emissions (EPA, 2013b), capture the real-world emission characteristics much better, particularly for more-recent-MY vehicles.

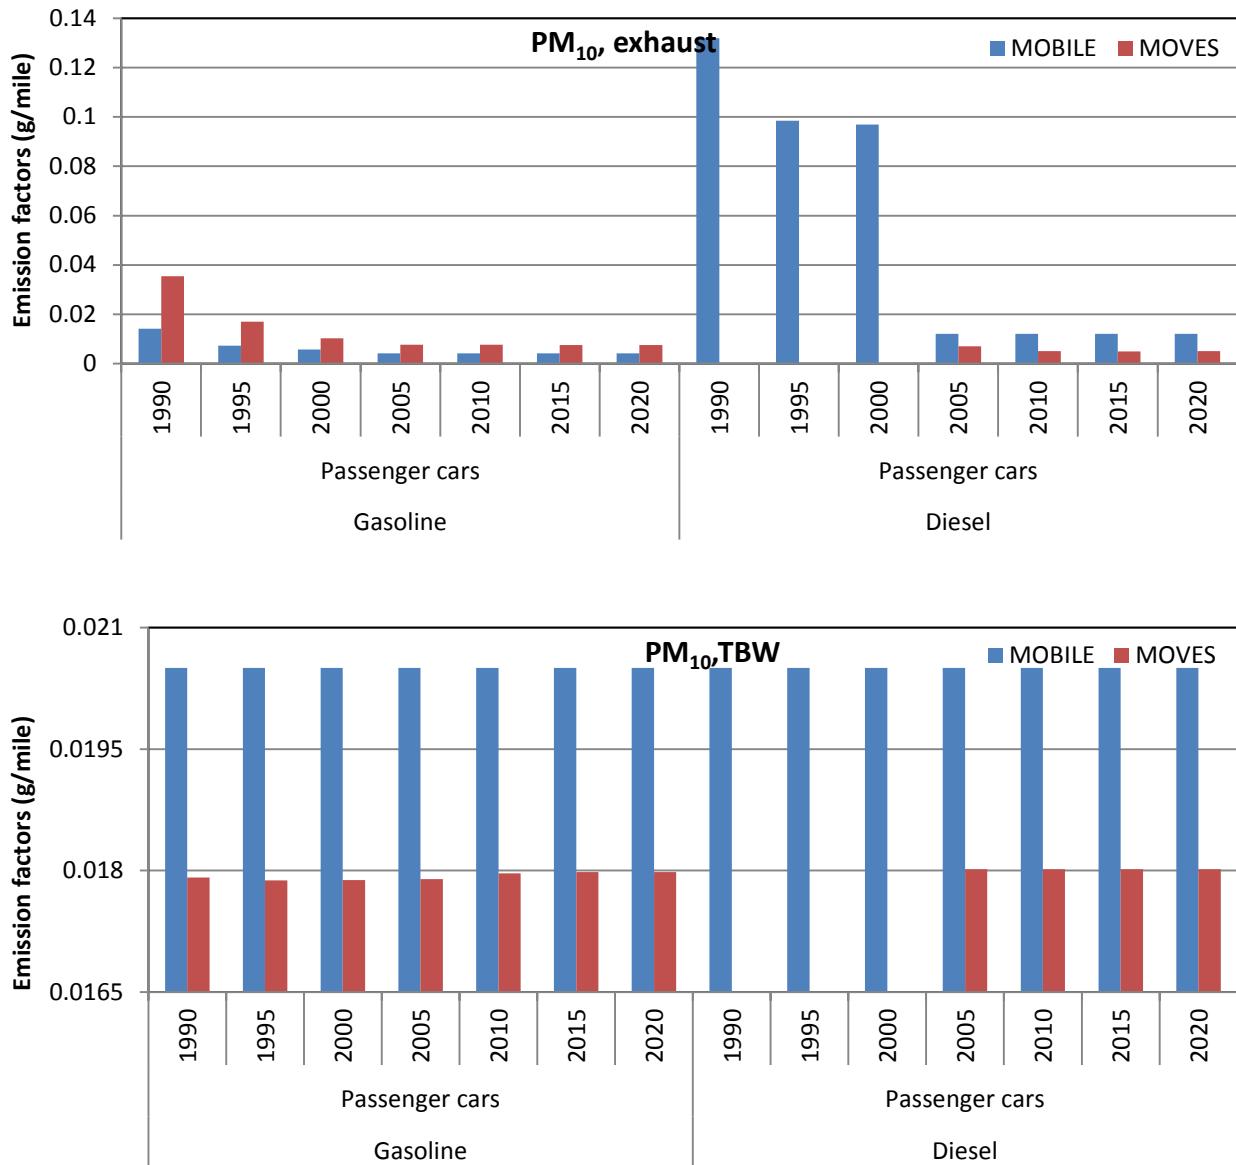

Figure 2 Comparison of air pollutant emissions factors generated by MOBILE6.2 and MOVES2010b for gasoline and diesel passenger cars. TBW refers to tire and brake wear.

3.4 Urban Shares of Vehicle Operations

We evaluated the urban shares of vehicle operations on the basis of urban vehicle miles traveled by vehicles (FHWA, 2011). Table 1 summarizes the urban shares of vehicle operations by state and on the U.S. average.

State	Vehicle operations	State	Vehicle operation						
CT	88%	NY	75%	KS	51%	TN	60%	MT	25%
DE	69%	PA	64%	KY	42%	WI	47%	UT	70%

Light-Duty Diesel Trucks 3 and 4 (6,001–8,500 lb GVWR)	LDDT34	0%	0%	0%	0%	0%	0%

a: Loaded vehicle weight, which is the weight of vehicle sitting empty (curb weight) plus 300 lbs;

b: Adjusted loaded vehicle weight, which is the average of the gross vehicle weight and the curb weight.
